# Baby42

A simple RISC processor

Jecel Mattos de Assumpção Jr April 2020

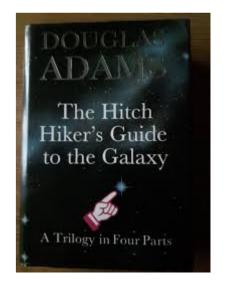

#### name

 The Manchester Baby (Small-Scale Experimental Machine – SSEM) ran a stored memory program in June 1948  4 bytes (32 bits) of data with 2 bytes of instruction

• And:

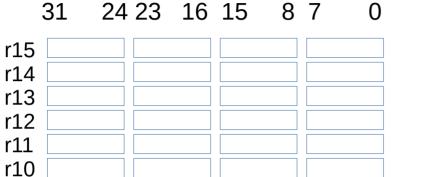

#### General purpose registers

state

**Program Counter** 

r9 r8 r7 r6 r5

r4 r3

r2

r1 r0 31 24 23 16 15 8 7 0

17 words = 68 bytes = 136 hexadecimal digits + external memory

Manchester Baby: 3 registers + 32 words of memory of 32 bits each

# RISC style

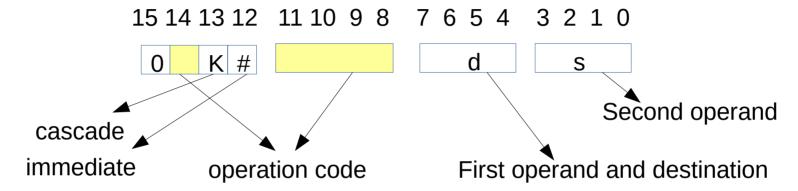

#### Two instruction formats:

- Data manipulation instructions only operate on registers, or a register and an immediate value present in the instruction itself
- Data storage transfer a register to/from memory (jump and link has the same format, though it should be considered a third kind of instruction)

# RISC: how many instructions?

- Counting all variations in assembly syntax we have 106 standard instructions and 12 optional ones (multiplication)
- Not counting the variations we have 30 standard instructions and 3 optional ones
- The control unit deals with only five instruction types:
  - 1)ALU (Math, Logic and Multiply)
  - 2)Comparison
  - 3)Load
  - 4)Store
  - 5) Jump and Link

# Data Manipulation Instructions

30 of the 32 possible op codes are used, but due to # and K nearly all instructions have 4 variations.

The assembly language syntax is C-like, with an addition being indicated by

$$rD += rS$$

#### # - Immediate values

"immediate" changes the second operand to be a number from -6 to 7 instead of a register. The value -7 (9 in hex) indicates that the actual operand is the next 16 bits and -8 (8 in hex) indicates 32 bits

In assembly, a # character is placed before the second operand to indicate that it is an immediate. Otherwise the numbers 0 to 15 indicate a register.

#### K - Cascade

"cascade" changes the destination to be the first operand of the following instruction. A sequence like

```
r3 <<= #2 ; multiply by four r3 += r1
```

can be implemented with cascade as

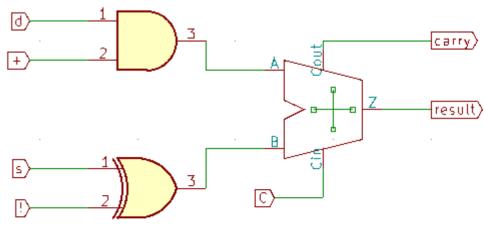

Unlike the original code fragment, these two instructions don't destroy the value in r3. So though the architecture is a two address in general, it can have the functionality of three addresses (actually four) when needed. The second instruction's syntax is changed from "d op= s" to "d =  $\{...\}$  op s" and the cascaded instruction is placed in the curly brackets also in infix form. It is possible to have more than one level of cascade, but then the d field of intermediate instructions is wasted.

### Math: op code is 0 0+!C

+ means that the destination is added to the source

 ! means that the source is bitwise inverted (one's complement)

C means that the carry in is set

### Math

IVICELII						
		0?ds	1?ds	2?ds	3?ds	
?0ds	move	d = s	d = #s			
?1ds	increment	d = s+1	d = #s+1			
?2ds	invert	d = !s	d = !#s			
?3ds	negate	d = ~s	d = ~#s			
?4ds	add	d += s	d += #s	$\{d + s\}$	$\{d + \#s\}$	
?5ds	add forcing carry	d += s+1	d += #s+1	$\{d + s+1\}$	{d + #s+1}

# Comparison (trivia)

The comparison instructions will produce a 0 or a 1 result for the next instruction when cascade is used or will skip the next instruction in the normal case when the comparison fails (note that d is not modified)

Note that a comparison that wants less than results can use greater than and swap the operands. This doesn't work if the second operand is an immediate value, but since "if (r3<200) x1 else x2" does the same thing as "if (r3>=200) x2 else x1" it is normally not a problem.

The "d  $\geq$  s" instruction can be used as a "borrow on subtract" to complement the "d ++ s" (carry on add) instruction.

# Data Storage Instructions

Store	8tbs	b[s] = t	9tbs	b[#s] = t
Load	Atbs	t = b[s]	Btbs	t = b[#s]
Jump and Link	Ctbs	====> b[s]/t	Dtbs	====> b[#s]/t
	E???		F???	

# Jump and Link

In the case of JL the t register will hold the previous value of the PC (unless t is 15, in which case the old value of the PC is discarded. "/t" can be omitted).

```
CFbs ====> b[s]
DFbs ====> b[#s]
```

The new value of the PC will be the sum of b and s (unless b is 15, in this case it will be the sum of s and the previous value of the PC. The "b" can be omitted).

```
CtFs ====> [s]/t
DtFs ====> [#s]/t
CFFs ====> [s]
DFFs ====> [#s]
```

Syntatic sugar for the assembler allows "====> label" and "====> label/t" to be written in place of "====> [#label-.]" and "====> [#label-.]/t" respectively.

# Load/Store Adapter (optional)

Baby42 natively only transfers 32 bit words to and from memory. It is possible to have an adapter circuit between the processor and memory/cache to make 16 and 8 bit transfers possible, as well as allowing non aligned 32 bit transfers (addresses that are not a multiple of 4).

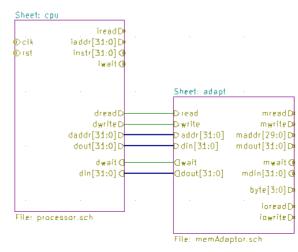

Bits 31 and 30 of an address indicate the size of the data to be fetched or stored while the rest of the address points to one of 1G bytes:

00 = 8 bit value

01 = 16 bit value

10 = 32 bit value

11 = I/O (32 bit value)

# Assembly language directives: define

Symbols can be defined by

name: expression

A period character in an expression indicates the value of the PC for that instruction. An empty expression is equivalent to just a period, so is equivalent of defining a label in other assemblers. This means that labels must be on a line of their own instead of coming before an instruction.

# Assembly language directives: origin

The value of the PC can be changed with

% expression

This is equivalent of "org" in other assemblers. If 120 bytes need to be allocated, then "% .+120" will do the job.

Instructions should always be aligned on an even byte. This expression can force that to be the case:

# Assembly language directives: constants

Constants can be inserted into the instruction stream with

# expr1, expr2, expr3, B# expr4, expr5, H# expr6, # expr7, expr8

The # interprets the following expressions as 32 bit values, while B# inserts 8 bit values and H# 16 bit values.

Placing ASCII characters between two "has the same effect as B# followed by the list of the characters' numeric value.

### Example 1

Jan Gray used this simple C program to illustrate the assembly language of his XR16 processor (http://www.fpgacpu.org/papers/xsoc-series-drafts.pdf)

```
typedef struct TN {
  int k;
  struct TN *left, *right;
} *T;

T search(int key, T p) {
  while (p && p->k != key)
   if (p->k < key)
      p = p->right;
  else
      p = p->left;
  return p;
}
```

```
; Example 1 Baby42 machine language and assembly with LCC style
              k: 0
              left: 4
              right: 8
              search: ; r3=key r4=p r9=scratch r2=return

# Example 2

Here is the famous Sieve of Eratosthenes benchmark published in Byte magazine:

```
1 \text{ SIZE} = 8190
2 DIM FLAGS(8191)
3 PRINT "Only 1 iteration"
5 \text{ COUNT} = 0
6 \text{ FOR I} = 0 \text{ TO SIZE}
7 \text{ FLAGS (I)} = 1
8 NEXT I
9 FOR I = 0 TO SIZE
10 IF FLAGS (I) = 0 THEN 18
11 PRIME = I+I+3
12 K = I + PRIME
13 IF K > SIZE THEN 17
14 FLAGS (K) = 0
15 K = K + PRIME
16 GOTO 13
17 \text{ COUNT} = \text{COUNT} + 1
18 NEXT I
19 PRINT COUNT," PRIMES"
```

```
size: 8190
          true: r10
          false: r11
          flags: r12
          flg:
                                                 DDF9 ???? ===> PrintText/r13
????? .. ?? % .+8191
                                                                 ; library subroutine expects
          count: r1
                                                                 ; return address in r13
          i: r2
                                                  1010
                                                                count = #0
          prime: r3
                                                  1020
                                                                i = #0
          k: r4
                                                            for1:
          text1:

DFF9 ????
```

There is also a C version of the benchmark in the Wikipedia article

(https://en.wikipedia.org/wiki/Byte\_Sieve). But Basic, specially a version as primitive as this, corresponds a lot more directly to the assembly language implementation.

Normally code that calls other subroutines should save the return address on the stack, but in this case we end with a jump instead of a return.

Since the address of flags happens to be 0 (it is a byte pointer), it would be possible to use "i[#FLG]" in the load and store instructions instead of "flag[i]", which would save one register. But that is not something that would normally happen, so it wasn't used in this example either.

# Example 3: ARM and Baby42

```
AREA LOG. CODE. READONLY
                                                                                ; AREA LOG, CODE, READONLY
EXPORT log
                                                                                : EXPORT log
r0 = input variable n
                                                                                : r0 = input variable n
; r0 = output variable m (0 by default)

# What is missing?

- No floating point math
- No interrupts
- No exceptions (if the missing op codes are defined as either NOPs or redundant)
- No MMU (memory management unit) or supervisor mode
- No debug interface (JTAG or control panel)
